FIELD OF THE INVENTION

- 15 This invention relates to compounds which mimic the chemical and/or biological activity of discodermolide, and to methods and intermediates useful in their preparation.

BACKGROUND OF THE INVENTION

- 20 In 1990, Gunasekera and co-workers at the Harbor Branch Oceanographic Institute reported the isolation of (+)-discodermolide (1), an architecturally novel metabolite of the marine sponge *Discodermia dissoluta* (0.002% w/w). (See,

Gunasekera, et al., *J. Org. Chem.* 1990, 55, 4912. Correction:
J. Org. Chem. 1991, 56, 1346).

(+)-1

Initial studies revealed that (+)-discodermolide
5 suppresses both the two-way mixed-lymphocyte reaction and the
concanavalin A-induced mitogenesis of murine splenocytes in
vitro with no associated cytotoxicity. Moreover, (+)-1
suppresses the *in vivo* graft-vs.-host splenomegaly response
induced by injection of parental splenocytes into F1 recipient
10 mice, with potency intermediate between those of cyclosporin
A and FK506. (Longley, et al., *Transplantation* 1991, 52, 650;
Longley, et al., *Transplantation* 1991, 52, 656; Longley, et al.
Ann. N.Y. Acad. Sci. 1993, 696, 94). These findings stimulated
the recent discovery that (+)-1 arrests cell development at the
15 M phase by binding and stabilizing mitotic spindle
microtubules; thus discodermolide resembles taxol in its mode
of action, but the microtubule binding affinity of 1 is much
higher. (ter Haar, et al., *Biochemistry* 1996, 35, 243; Hung,
et al., *Chemi. & Biol.* 1996, 3, 287). These and other results
20 suggest that (+)-discodermolide holds considerable promise as
an anticancer agent. The scarcity of natural material however
has precluded a complete evaluation of its biological profile.

The absolute configuration of discodermolide remained undefined until Schreiber et al. synthesized both antipodes of 1. (Nerenberg, et al. *J. Am. Chem. Soc.* **1993**, *115*, 12621; Hung, et al., *Chem. & Biol.* **1994**, *1*, 67). Interestingly, the 5 unnatural (-) antipode also displays significant immunosuppressant activity.

There is, therefore, a need for improved synthetic methods for the preparation of polyhydroxy, dienyl lactones such as the discodermolides, as well as a need for compounds 10 having similar chemical and/or biological activity.

OBJECTS OF THE INVENTION

It is one object of the present invention to provide polyhydroxy, dienyl lactones and mimics thereof.

It is a further object to provide processes for the 15 preparation of such compounds and their mimics.

It is another object of this invention to provide intermediates useful in such processes.

20 DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

It has been found in accordance with the present invention that the synthesis of polyhydroxy, dienyl lactones such as the discodermolides can be achieved by highly convergent and stereocontrolled synthetic procedures.

25

As shown in Figure 1 for the (-)-discodermolide antipode, our analysis revealed a repeating triad of contiguous stereocenters, separated by Z-olefinic linkages at C(8,9) and C(13,14). Disconnections at C(8,9), C(14,15) and C(21,22) generated fragments A, B and C, each deriving in turn
30 from a common precursor (5) containing the recurring stereochemical triad.

As shown in Figure 2, precursor 5 was prepared by a synthetic procedure whereby hydroxy ester (-)-6 was protected as the *p*-methoxybenzyl (PMB) ether by treatment with the Bundle trichloroimidate reagent 7 under acidic conditions.

5 Reduction with LiAlH_4 provided the alcohol (-)-8 after distillation. Swern oxidation, Evans aldol condensation, and Weinreb amide formation completed the construction of common precursor (+)-5. This concise five-step synthesis could be routinely carried out on a 50-g scale in 59% overall yield.

10 Alternatively, as shown in Figure 37, Swern oxidation of (+)-8 followed by the addition norephedrine derived oxazolidinone 61 results in a crystalline product 62 which, in turn, can be converted to common precursor (-)-5.

In view of the polypropionate structure of the A
15 fragment, we performed a second asymmetric aldol reaction, as shown in Figure 3. Initial formation of the *p*-methoxybenzylidene acetal (-)-11 from common precursor (-)-5 (78% yield) was designed to allow selective deprotection of C(21) and C(19) hydroxyls for introduction of the terminal
20 diene and carbamate moieties. Following reduction of amide (-)-11 to the aldehyde (80% yield), (aldol reaction with oxazolidinone (+)-9 (80% yield) provided alcohol (+)-13 which incorporated the five stereocenters of subunit A. The structure of (+)-13 was confirmed by single-crystal X-ray
25 analysis. Protection of the secondary alcohol as the TBS ether and removal of the chiral auxiliary (LiBH_4 , EtOH, THF) afforded primary alcohol (-)-15 (81% yield, two steps), which could be efficiently converted either to tosylate (-)-16 or iodide (-)-A.

30 As outlined in Figure 1, our strategy required a Z vinylic halide B for coupling with fragment A. Beginning again with the common precursor (+)-5, TBS protection (Figure 4) followed by reduction of the Weinreb amide [DIBAL (2

equiv), THF, -78 °C] (Kim, et al., *Tetrahedron Lett.* 1989, 30, 6697) afforded aldehyde (+)-18 in 88% yield for the two steps. We adopted a stepwise approach to introduction of the vinyl halide, whereby (+)-18 was converted to the Z α -bromo
5 unsaturated ester (-)-19 ($\text{Ph}_3\text{PCBrCO}_2\text{Et}$, PhH, reflux; 75% yield after chromatography). Reduction to allylic alcohol (-)-20 followed by mesylation and displacement with LiBHET_3 then furnished Z vinyl bromide (-)-22 in 77% overall yield from 19.

One preferred synthetic strategy utilized a vinyl
10 iodide as the desired B segment. Synthesis of (-)-B was achieved by direct olefination of aldehyde (+)-18 (41%, 6:1 Z/E) (Figure 9), followed by chromatographic removal of the undesired E product. Alternatively, the B segment can be prepared by the two routes shown in Figure 39. The first
15 involves an α -iodo sulfone 69 to effect a one-step installation of the vinyl iodide. The second exploits the enhanced reactivity of the trans iodide of diiodide 70.

Our preferred synthetic strategy involves selective removal of a primary PMB ether in the presence of a PMP acetal
20 in the AB coupling product ((-)-39, Figure 5). A 1:1 mixture of PMB ether (-)-22 and PMP acetal (-)-15 was exposed to DDQ (1.1 equiv) in $\text{CH}_2\text{Cl}_2/\text{H}_2\text{O}$ (Figure 6). The acetal (-)-15 largely remained intact while the debenzylated alcohol (-)-25 was formed in 83% yield.

25 As shown in Figure 7, we again utilized the TBS ether (+)-17 for the preparation of C from common precursor (+)-5. Oxidative cleavage of the PMB group (DDQ, CH_2Cl_2 , H_2O) provided alcohol 26 in variable (60-86%) yields, accompanied by the corresponding lactone. Hydrogenolysis with Pearlman's
30 catalyst afforded (+)-26 in 92% yield. Exposure of the alcohol to $\text{SO}_3\cdot\text{pyr}$ furnished aldehyde (+)-27 (98% yield), which in turn was converted to dithiane (+)-28 (79%). In the latter step, our modification of the Evans protocol for dithiane

generation [(TMSSCH₂)₂CH₂, ZnCl₂, Et₂O] minimized elimination of the TBS ether to form the α,β-unsaturated amide. Following reduction to aldehyde (+)-29 with DIBAL (91% yield), dimethyl acetal formation gave (+)-30 (99%). The coupling of dithiane
5 30 with R-(-)-glycidyl benzyl ether [(-)-31] then afforded alcohol (-)-32 in 79% yield. Unmasking of the ketone moiety [(CF₃CO₂)₂IPh, 80%] and Evans stereocontrolled reduction (97%) provided the anti diol (-)-34, which embodied all of the stereocenters in fragment C.

10 Acid-catalyzed cyclization of (-)-34 (TsOH, room temperature) provided methoxy pyran 35 in 87% yield as a 1:2 mixture of α and β anomers (Figure 8). Debenzylation (H₂, Pd/C) of 36 afforded alcohol 37 quantitatively. Exposure to EtSH and MgBr₂ in Et₂O then gave a separable 6:1 mixture of β
15 ethyl hemithioacetal (+)-38 and its α anomer in 83% yield. Swern oxidation of (+)-38 furnished the final fragment (+)-C in 86% yield.

 Reaction of (-)-B with the organozinc derivative of (-)-A (Figure 10) was achieved by premixing iodide A with
20 dried solid ZnCl₂ (ether, -78 °C) before addition of t-BuLi. It is believed that three equivalents of t-BuLi are required for complete consumption of (-)-A, probably because the first equivalent reacts with ZnCl₂. This modification increased the yield to 66% after flash chromatography.

25 Conversion of the Z trisubstituted olefin (-)-39 to the phosphonium iodide (-)-49 began with selective removal of the PMB group, as in our model study (DDQ, CH₂Cl₂, H₂O), furnishing (-)-40 in 87% yield (Figure 11). As shown in Figure 12, alcohol (-)-40 furnished the requisite iodide 42
30 almost exclusively, as indicated by NMR examination of the crude material. The very sensitive iodide was used without purification. Thorough mixing of iodide 42 with I-Pr₂NEt (3 equiv) followed by exposure to excess PPh₃ (15 equiv) without

solvent at 80 °C generated (-)-49 in 37% yield for the two steps. The major by-product was characterized as (-)-50 (35% yield). The unsaturated model alcohol (+)-44 similarly afforded the Wittig salt (+)-46 in low yield (Figure 13),
5 whereas the saturated derivative (+)-51 gave phosphonium iodide (+)-53 almost quantitatively.

Our preferred method to prepare compound 49 entails the mixing of iodide 42 with *I*-Pr₂NEt (0.5 equiv.) and PPh₃ (4 equiv.) in benzene/toluene (7:3) and subjecting this mixture
10 to an applied pressure of 10-15 Kbar.

As shown in Figure 14, assembly of the discodermolide backbone entailed Wittig coupling of aldehyde C with the ylide derived from AB phosphonium salt (-)-49 to install the C(8,9) Z alkene in (-)-54 (>49:1 Z/E, 76% yield). DIBAL reduction
15 (88% yield) followed by oxidation of the resultant primary alcohol (-)-55 then produced aldehyde (-)-56 (96%). The terminal Z diene (-)-57 was elaborated via the Yamamoto protocol in 70% yield with excellent selectivity (16:1 Z/E). After flash chromatography, hydrolysis of the hemithio acetal
20 and mild DMSO/Ac₂O oxidation provided lactone (-)-58 in 82% yield for the two steps. Removal of the PMB group (DDQ, CH₂Cl₂, H₂O, 95% yield) and carbamate formation (Cl₃CONCO, CH₂Cl₂, neutral Al₂O₃, 83%) afforded tris(TBS ether) (-)-60. Final deprotection with 48% HF/CH₃CN (1:9) furnished
25 (-)-discodermolide, identical with an authentic sample (Figure 15).

Alternatively, lactone 58 can be prepared by the Wittig coupling of aldehyde 67 with the ylide derived from 49, as shown in Figure 42. Regioselective ring opening of
30 benzylidene acetal 76 with DIBAL followed by oxidation with pyridinium dichromate affords aldehyde 77. Application of the Yamamoto olefination protocol affords compound 58. Alternatively, the diene installation can be effected using an

alkyl chromium reagent generated by the procedure of Hodgson, *et al.*, *Tetrahedron Letters* 1992, 33, 4761. The aldehyde 67 can be prepared by from compound (-)-27 (prepared generally according to the procedure of Smith, *et al.*, *J. Am. Chem. Soc.* 1995, 117, 12011) by effecting a Mukaiyama aldol reaction between aldehyde 27 and enol ether 63 to form enone 64. Reduction of enone 64 furnished a 9:1 mixture of carbinols, favoring the desired isomer. Protection of the newly formed carbinol with TBSCl and subsequent ozonolysis of the trisubstituted olefin provides 67 in approximately 80% overall yield, as shown in figure 38..

Alternatively, the discodermolide backbone can be synthesized by installing the terminal diene before Wittig coupling with Fragment C. As shown in Figure 40, regioselective ring opening of benzylidene acetal 39 with DIBAL-H followed by oxidation and application of the Yamamoto olefination protocol provides diene 73. Selective removal of the less hindered PMB using DDQ/H₂O is followed by conversion to the primary iodide and phosphonium salt 75. Alternatively, the primary PMB can be enhanced for either a dimethoxy benzyl ether or silyl protecting group earlier in the sequence. Application of Dauben's high pressure conditions results in approximately 75% yield of the desired phosphonium salt. Further assembly of the discodermolide backbone entails Wittig coupling of aldehyde 67 with the ylide derived from phosphonium salt 75 to afford 58. Further manipulation as indicated above (Figure 15) provides (+)-discodermolide.

Another preferred route to phosphonium salt 75 is depicted in Figures 43 and 44. Starting from alcohol 40, trityl ether 87 may be prepared by contacting with trityl chloride and N,N-dimethyl-pyridine (DMAP) in hot pyridine (Figure 43). Reductive opening of the anisylidene acetal functionality of 87 with DIBALH provides the primary alcohol

88. Oxidation of 88 with Dess-Martin Periodane (DMP) followed by Yamamoto olefination provides diene 90 with approximately a 8-11:1 diastereoselectivity.

The trityl protecting group of 90 is preferably removed utilizing a modified Boeckman protocol, as described, for example, in Boeckman, R. K., Jr.; Potenza, J. C. *Tetrahedron Lett.* 1985, 26, 1411, the disclosure of which is hereby incorporated by reference in its entirety, to provide alcohol 74. (Figure 44). Wittig salt 75 may be prepared via conversion of alcohol 74 to the corresponding iodide employing a modified Corey protocol (PPh_3 , I_2 , $\text{PhH/Et}_2\text{O}$) and subsection of the unstable iodide to excess PPh_3 at high pressure (12.8 Kbar) in a buffered, non-polar medium (Hunig's base, toluene/benzene).

Treatment of tetraene 58 (a mixture of diene isomers; ca 8-12:1) with DDQ results in oxidative removal of the PMB ether and, selective destruction of the trans-diene impurity preferably yields diastereomerically pure alcohol 59 after flash chromatography (Figure 45).

Alcohol 59 may be subjected to the Kocovsky protocol to yield the carbamate 60 (Scheme 46). Carbamate 60 is preferably taken onto the natural product (+)-discodermolide by slow addition of acid, for example, 3N HCl to a methanol solution of 60 over a suitable time period such as 12 hours. Discodermolide may be purified by flash chromatography followed by crystallization from, for example, neat acetonitrile.

An Aldol reaction between aldehyde 92 and the corresponding enolate of amide 93 yields the common precursor 5 in three steps (Figure 47). Amide 93 can be easily prepared from the commercially available acid chloride 94 (Figure 48).

Alternative synthetic routes to tetraene 58 are depicted in Figures 49 and 50. A palladium catalyzed coupling

between vinyl iodide 96 and organozinc 97 yields 58 (Figure 49). Alternatively 58 can be constructed via the coupling of 98 with aldehyde 67 (Figure 50).

30 and are covalently bound to other groups through the alkyl portion, as in a benzyl group. Alkheteroaryl groups are groups that contain alkyl and heteroaryl portions and are covalently bound to other groups through the alkyl portion.

The target compounds and intermediates of the present
35 invention may contain protecting groups. Protecting groups are known *per se* as chemical functional groups that can be

selectively appended to and removed from functionality, such as hydroxyl and amine groups, present in a chemical compound to render such functionality inert to certain chemical reaction conditions to which the compound is exposed. See, e.g., Greene and Wuts, Protective Groups in Organic Synthesis, 2d edition, John Wiley & Sons, New York, 1991. Numerous hydroxyl protecting groups are known in the art, including the acid-labile *t*-butyldimethylsilyl, diethylisopropylsilyl, and triethylsilyl groups and the acid-stable aralkyl (e.g., benzyl), triisopropylsilyl, and *t*-butyldiphenylsilyl groups. Useful amine protecting groups include the allyloxycarbonyl (Alloc), benzyloxycarbonyl (CBz), chlorobenzyloxycarbonyl, *t*-butyloxycarbonyl (Boc), fluorenylmethoxycarbonyl (Fmoc), isonicotinyloxycarbonyl (I-Noc) groups.

As used herein, the term "oxidatively labile group" is intended to include all groups known to be removed by an oxidizing agent. An example of an oxidizing agent includes, but is not limited to, 2,3-dichloro-5,6-dicyano-1,4-benzoquinone (DDQ).

The term amino acid as used herein is intended to include all naturally-occurring and synthetic amino acids known in the art. In general, amino acids have structure $H_2N-CH(R_C)-C(O)OH$ where R_C is the amino acid side chain. Representative, naturally-occurring side chains are shown in Table 1.

20 The compounds of the present invention can be admixed with carriers, excipients, and/or diluents to form novel compositions. Such compositions can be used in prophylactic, diagnostic, and/or therapeutic techniques. By administering an effective amount of such a composition, prophylactic or
25 therapeutic responses can be produced in a human or some other type mammal. It will be appreciated that the production of prophylactic or therapeutic responses includes the initiation or enhancement of desirable responses, as well as the mitigation, cessation, or suppression of undesirable responses.

30 The compositions of the invention are expected to find use, for

example, in the inhibition of undesired cell proliferation (e.g., cancer) and in the inhibition of rejection in organ transplantation procedures. (See, e.g., Longley, et al., *Transplantation* 1991, 52, 650 and 656).

5 Compositions of the invention can be prepared by any of the methods well known in the pharmaceutical art, for example, as described in *Remington's Pharmaceutical Sciences* (Mack Pub. Co., Easton, PA, 1980). The compositions can include a compound of the invention as an active ingredient in admixture
10 with an organic or inorganic carrier or excipient suitable, for example, for oral administration. Other suitable modes of administration will be apparent to those skilled in the art. The compound of the invention can be compounded, for example, with the usual non-toxic, pharmaceutically acceptable carriers
15 for tablets, pellets, capsules, solutions, suppositories, suspensions, and any other form suitable for use. The carriers which can be used are water, glucose, lactose, gum acacia, gelatin, mannitol, starch paste, magnesium trisilicate, talc, corn starch, keratin, colloidal silica, potato starch, urea and
20 other carriers suitable for use in manufacturing preparations, in solid, semisolid, or liquid form, and in addition auxiliary, stabilizing, thickening and coloring agents and perfumes may be used. The compound of the invention is included in the pharmaceutical composition in an amount sufficient to produce
25 the desired effect upon the process or condition of diseases.

For oral administration, tablets containing various excipients such as microcrystalline cellulose, sodium citrate, calcium carbonate, dicalcium phosphate and glycine may be employed along with various disintegrants such as starch and
30 preferably corn, potato or tapioca starch, alginic acid and certain complex silicates, together with granulation binders like polyvinylpyrrolidone, sucrose, gelatin and acacia. Additionally, lubricating agents such as magnesium stearate, sodium lauryl sulfate and talc are often very useful for
35 tableting purposes. Solid compositions of a similar type may also be employed as fillers in appropriately soluble (e.g.,

gelatin) capsules; preferred materials in this connection also include lactose or milk sugar as well as high molecular weight polyethylene glycols.

When aqueous suspensions and/or elixirs are desired for oral administration, the active ingredient may be combined with various sweetening or flavoring agents, coloring matter or dyes, and, if so desired, emulsifying and/or suspending agents as well, together with such diluents as water, ethanol, glycerin and various like combinations thereof.

For parenteral administration, suspensions containing a compound of the invention in, for example, aqueous propylene glycol can be employed. The suspensions should be suitably buffered (preferably pH>8) if necessary and the liquid diluent first rendered isotonic. The aqueous suspensions are suitable for intravenous injection purposes. The preparation of such suspensions under sterile conditions is readily accomplished by standard pharmaceutical techniques well-known to those skilled in the art. Additionally, it is possible to administer the compounds of the invention topically and this may preferably be done by way of creams, jellies, gels, pastes, ointments and the like, in accordance with standard pharmaceutical practice.

The compounds of the invention can be employed as the sole active agent in a pharmaceutical composition or can be used in combination with other active ingredients, e.g., other agents useful in diseases or disorders.

The amount of active ingredient that is to be combined with the carrier materials to produce a single dosage form will vary depending upon the host treated and the particular mode of administration. The specific dose level for any particular patient will depend on a variety of factors including the activity of the specific compound employed, the age, body weight, general health, sex, diet, time of administration, route of administration, rate of excretion, drug combination, and the severity of the particular disease undergoing therapy. In some instances, dosage levels below the lower limit of the aforesaid range may be more than adequate, while in other cases

still larger doses may be employed without causing any harmful side effects provided that such higher dose levels are first divided into several small doses for administration throughout the day. The concentrations of the active ingredient in therapeutic compositions will vary depending upon a number of factors, including the dosage of the drug to be administered, the chemical characteristics (e.g., hydrophobicity) of the active ingredient, and the route of administration. Typical dose ranges are from about 285 $\mu\text{g/kg}$ of body weight per day in three divided doses; a preferred dose range is from about 42 $\mu\text{g/kg}$ to about 171 $\mu\text{g/kg}$ of body weight per day. The preferred dosage to be administered is likely to depend on such variables as the type and extent of progression of the disease or disorder, the overall health status of the particular patient, the relative biological efficacy of the compound selected, and formulation of the compound excipient, and its route of administration, as well as other factors, including bioavailability, which is in turn influenced by several factors well known to those skilled in the art.

Additional objects, advantages, and novel features of this invention will become apparent to those skilled in the art upon examination of the following examples thereof, which are not intended to be limiting.

All reactions were carried out in oven-dried or flame-dried glassware under an argon atmosphere, unless otherwise noted. All solvents were reagent grade. Diethyl ether and tetrahydrofuran (THF) were freshly distilled from sodium/benzophenone under argon before use. Dichloromethane, benzene and diisopropyl amine were freshly distilled from calcium hydride before use. Triethylamine and diisopropylethylamine were distilled from calcium hydride and stored over potassium hydroxide. Hexamethylphosphoramide was freshly distilled from calcium hydride. Anhydrous pyridine, dimethylformamide and dimethyl sulfoxide were purchased from Aldrich and used without purification. *n*-Butyllithium and *t*-butyllithium were purchased from Aldrich and standardized by titration with diphenylacetic acid.

Unless stated otherwise all reactions were magnetically stirred and monitored by thin layer chromatography using 0.25 mm E. Merck pre-coated silica gel plates. Flash column chromatography was performed with the indicated solvents using 5 silica gel-60 (particle size 0.040-0.062 mm) supplied by E. Merck. Yields refer to chromatographically and spectroscopically pure compounds, unless otherwise stated.

All melting points were determined on a Bristoline heated-stage microscope or a Thomas-Hoover apparatus and are 10 corrected. The IR and NMR were obtained for CHCl_3 and CDCl_3 solutions respectively unless otherwise noted. Infrared spectra were recorded with a Perkin-Elmer Model 283B spectrometer using polystyrene as an external standard. Proton NMR spectra were recorded on a Bruker AM-500 spectrometer. 15 Carbon-13 NMR spectra were recorded on a Bruker AM-500 or AM-250 spectrometer. Chemical shifts are reported relative to internal tetramethylsilane (δ 0.00) for proton and chloroform (δ 77.0) or benzene (δ 128.0) for carbon-13. Optical rotations were obtained with a Perkin-Elmer model 241 polarimeter in the 20 solvent indicated. High-resolution mass spectra were obtained at the University of Pennsylvania Mass Spectrometry Service Center on either a VG micromass 70/70H high resolution double-focusing electron impact/chemical ionization spectrometer or a VG ZAB-E spectrometer. Microanalyses were 25 performed by Robertson Laboratories, Madison, New Jersey. Single-crystal X-ray diffraction structure determination were performed at the University of Pennsylvania using an Enraf Nonius CAD-4 automated diffractometer. High performance liquid chromatography (HPLC) was performed using a Ranin component 30 analytical/semi-prep system.

EXAMPLE 1

Alcohol (-)-8.

p-Methoxybenzyl alcohol (200 g, 1.45 mol) was added to a suspension of NaH (60% in mineral oil; 5.82 g, 0.146 mol) in 35 anhydrous ether (450 mL) over 1 h at room temperature. The mixture was stirred for 1 h and cooled to 0 °C.

Trichloroacetonitrile (158 mL, 1.58 mol) was then introduced over 80 min. After 1.5 h the solution was concentrated with the water bath temperature maintained below 40 °C. The residue was treated with a mixture of pentane (1.5 L) and MeOH (5.6 mL), 5 stirred at room temperature for 30 min, and filtered through a short Celite column. Concentration gave the trichloroimide (394.3 g) as a red oil which was used without further purification.

A solution of (R)-(-)-Roche ester (124.7 g, 1.06 mol) in 10 CH₂Cl₂/cyclohexane (1:2, 1.5 L) was cooled to 0 °C and treated with trichloroimide (364.3 g) and PPTS (13.3 g, 52.9 mmol). After 3 h, the mixture was warmed to room temperature, stirred for 40 h, and concentrated. Filtration through a short silica column (20% ethyl acetate/hexane) afforded the ester (303.5 g) 15 as a slight yellow oil.

The ester (303.5 g) was divided into three portions for the next reaction. In each preparation, solution of crude ester (112.8 g) in anhydrous THF (1.0 L) was cooled to 0 °C and LiAlH₄ (1.0 M in THF, 560 mL, 0.560 mol) was added over 1 h. 20 The mixture was warmed gradually to room temperature and stirred for 24 h. After dilution with ether (1.0 L) the mixture was cooled to 0 °C and quenched carefully with saturated aqueous Rochelle's salt (20 mL). The resultant mixture was then transferred to a 4-L flask, diluted with ether 25 (1.0 L), and treated with additional Rochelle's solution (ca. 300 mL) with shaking until a solid precipitated. The solution was filtered, concentrated, and the residue (including the aqueous layer) was diluted with ether (700 mL), dried over Na₂SO₄, filtered and concentrated. The crude products of the 30 three reactions were combined and distilled under vacuum, furnishing (-)-8 (142.7 g, 74% yield for two steps) as a colorless oil: $[\alpha]_D^{23}$ -16.9° @ 1.28, CHCl₃; IR (CHCl₃) 3510 (m), 3015 (s), 2965 (s), 2940 (s), 2920 (s), 2870 (s), 2840 (m), 1618 (s), 1590 (m), 1517 (s), 1470 (s), 1445 (m), 1423 (m), 1365 (m), 1305 (s), 1250 (s), 1178 (s), 1092 (s), 1037 35 (s), 826 (m), 814 (m), 718 (w), 710 (w) cm⁻¹; ¹H NMR (500 MHz,

From vinyl bromide (-)-22: A solution of (-)-22 (3.78 g, 8.04 mmol) in HMPA/DMF (2:1, 6 mL) was added to a mixture of KI (4.15 g, 250 mmol), NiBr_2 (34.9 mg, 0.160 mmol), and Zn powder (23.2 mg, 0.355 mmol). The mixture was stirred at room temperature for 15 min then heated to 90 °C. The green color mixture turned black-brown after 5 min and dark green after 1 h. After additional 1 h at 90 °C, the mixture was cooled to room temperature, diluted with ethyl acetate (200 mL), washed with brine (4 x 200 mL), dried over MgSO_4 , filtered and concentrated. Flash chromatography (2% ethyl acetate/hexane) provided B (3.59 g, containing 13% unreacted vinyl bromide) as a colorless oil.

After an additional 10 min, the resultant red solution was added via cannula to a cooled (-78°C) solution of I_2 (8.02 g, 31.6 mmol) in THF (300 mL) over 15 min. The yellow slurry formed was stirred at -78 °C for 5 min and at -23 °C for 10 min. NaHMDS (1.0 M in THF, 31.0 mL, 31.0 mmol) was added over 8 min and the mixture stirred 15 min further. A solution of aldehyde (+)-18 (6.96 g, 18.3 mmol) in THF (50 mL) was introduced via cannula (10mL rinse), and the reaction mixture was stirred at -23 °C for 10 min, warmed to room temperature, stirred for 3 h, and then quenched with MeOH (10 mL). Following concentration and filtration through a silica column

A solution of alcohol (-)-40 (402.8 mg, 0.577 mmol) in $\text{PhH}/\text{Et}_2\text{O}$ (1:2, 45 mL) was treated with PPh_3 (532 mg, 2.03 mmol) and imidazole (158 mg, 2.32 mmol). After the imidazole dissolved, I_2 (437 mg, 1.72 mmol) was added under vigorous stirring. The mixture was stirred 2 h and then treated with NEt_3 (2 mL). Soc.* **1995**, 117, 12011) (1.15 g, 1.0 mmol) in anhydrous pyridine (10 mL) at 0 °C is treated with p-toluenesulfonyl chloride (286 mg, 1.5 mmol). The mixture is allowed to warm to room temperature for 4-6 h. The pyridine is removed in vacuo and the residue is purified by flash chromatography to afford tosylate 101.

B. Arene 102

Phenyllithium (2.7 mL, 1.8 M in cyclohexane-ether (70:30)) is added dropwise to a solution of copper (I) iodide (460 mg, 2.4 mmol) in anhydrous diethyl ether (5 mL) at 0 °C. To the resultant mixture is added a solution of tosylate 101 (780 mg,

0.6 mmol) in ether (5 mL) and the resultant mixture is warmed to room temperature with stirring. After 4 h, saturated aqueous ammonium chloride (20 mL) is added. The layers are separated and the aqueous layer is extracted with ethyl acetate. The combined organics are dried over magnesium sulfate and concentrated *in vacuo*. The residue is purified by flash chromatography to afford 102.

C. Lactol 103.

To a solution of 102 (120 mg, 0.1 mmol) in tetrahydrofuran-acetonitrile (15 mL, 2:1) is added phosphate buffer (pH 7, 5 mL) and mercury (II) chloride (272 mg, 1.0 mmol). The resultant mixture is stirred 1 h at room temperature. The reaction mixture is diluted with ether (100 mL) and washed with saturated aqueous brine (2 x 50 mL), dried over magnesium sulfate and concentrated *in vacuo*. The residue is purified by flash chromatography to afford 103 as a mixture of α and β anomers.

D. Lactone 104.

To a solution of 103 (84 mg, 0.070 mmol) in dimethyl sulfoxide (10 mL) is added acetic anhydride (2 mL). After 2 days at room temperature, the mixture is diluted with ether (100 mL) and washed with saturated aqueous sodium bicarbonate (50 mL), saturated aqueous brine (50 mL), dried over magnesium sulfate and concentrated *in vacuo*. The residue is purified by flash chromatography to afford 104.

E. Alcohol 105.

To a solution of 104 (56 mg, 0.050 mmol) in dichloromethane (3 mL) at 0 °C is added water (50 mL) and 2,3-dichloro-5,6-dicyano-1,4-benzoquinone (52 mg, 0.018 mmol). After 1 h, the reaction mixture is diluted with ethyl acetate (50 mL), washed with saturated aqueous brine (3 x 25 mL), dried over magnesium sulfate and concentrated *in vacuo*. The residue is purified by flash chromatography to afford 105.

F. Carbamate 106.

To a solution of 105 (10 mg, 0.010 mmol) in dichloromethane (2 mL) is added trichloroacetyl isocyanate

(0.12 mL, 1.00 mmol). After 30 min, the reaction mixture is diluted with dichloromethane (4 mL) and neutral alumina (1 g) is added. The resultant suspension is stirred an additional 4 h. The reaction mixture is filtered and the concentrated 5 filtrate is chromatographed on silica gel to afford 106.

G. Tetrol 107.

A solution of 106 (10 mg, 0.0096 mmol) in 48% hydrofluoric acid-acetonitrile (1:9, 2 mL) is stirred at ambient temperature. After 12 h, saturated aqueous sodium 10 bicarbonate (25 mL) is added and the mixture is extracted with ethyl acetate (3 x 20 mL). The combined organics are dried over magnesium sulfate and concentrated *in vacuo*. The residue is purified by flash chromatography to afford 107.

EXAMPLE 52 (Figures 18-20)

15 A. Alcohol 203.

To a slurry of powdered 4-Å molecular sieves (2.0 g) in 100 mL of anhydrous toluene is added boronate 202 (see, Roush, et al., *J. Am. Chem. Soc.* **1990**, 112, 6348) (170 mL, 1.0 M in toluene). The resultant solution is stirred 10 min at room 20 temperature and then cooled to - 78 °C. A solution of aldehyde 201 (see, Solladie, et al., *Tetrahedron Lett.* **1987**, 28, 797) (113 mmol) in toluene (100 mL) is added over a 2 h period, after which the reaction is maintained at -78 °C for 10 h. Excess ethanolic sodium borohydride (ca. 0.75 g/10 mL) is added 25 and the reaction mixture is warmed to 0 °C. Aqueous 1 N sodium hydroxide (300 mL) is added and the mixture is stirred vigorously for 2 h. The layers are separated and the aqueous layer is extracted with ether (5 x 300 mL). The combined organics are dried over potassium carbonate and concentrated 30 *in vacuo*. The residue is purified by flash chromatography to afford 203.

B. Bis-silyl ether 204

A solution of 203 (75 mmol) in dimethylformamide (150 mL) is cooled to 0 °C and treated with imidazole (150 mmol) and 35 tert-butyldimethylsilyl chloride (100 mmol). The resultant

solution is warmed to room temperature. After 12 h, the reaction mixture is poured into 1500 mL of water and extracted with ether (3 x 200 mL). The ethereal extracts are washed with water (2 x 50 mL) and saturated aqueous brine (50 mL), dried
5 over magnesium sulfate and concentrated *in vacuo*. The residue is purified by flash chromatography to afford 204.

C. Alcohol 205.

10 until the colorless solution is converted into a steel blue one. The crude reaction mixture is cautiously quenched with sodium borohydride (100 mmol) and the resultant solution is warmed to room temperature. After 3 h, the excess sodium borohydride is destroyed by the cautious addition of water.
15 The methanol is removed *in vacuo* and the residue is partitioned between saturated aqueous ammonium chloride (200 mL) and ethyl acetate (200 mL). The layers are separated and the aqueous layer is further extracted with ethyl acetate (2 x 100 mL). The combined organics are dried over anhydrous magnesium
20 sulfate and concentrated *in vacuo*. The residue is purified by flash chromatography to afford 205.

I. General procedure for synthesis of siloxy aldehydes

5 (85).

A. A solution of organolithium ($M = Li$, figure 41)) of type 80-83 (20 mmol) in ether (40 mL) is added slowly to a 0 °C solution of benzyl (S)-(+)-glycidyl ether (9 mmol) in ether (20 mL). The reaction is allowed to warm to room temperature.
10 After 18-24 h, the reaction mixture is quenched by the addition of tert-butyldimethylsilyl triflate (10 mmol) and poured into saturated aqueous sodium bicarbonate (100 mL). The aqueous layer is separated and extracted with ether (2 x 50 mL). The combined organics are washed with saturated aqueous brine (50
15 mL), dried over magnesium sulfate and concentrated in vacuo. The residue is purified by flash chromatography to afford an alpha-siloxy benzyl ether.

B. To a solution of the above benzyl ether (6 mmol) in ethyl acetate-ethanol (8:1, 90 mL) is added palladium on carbon
20 (10% wet, 500 mg). The mixture is stirred under hydrogen atmosphere for 3-6 h, then filtered and concentrated in vacuo. The residue is purified by flash chromatography to afford an alcohol.

C. Aldehyde 85.

25 Oxalyl chloride (1.5 mmol) is added dropwise to a -78 °C solution of dimethyl sulfoxide (3 mmol) in dichloromethane (4 mL). After 15 min, a -78 °C solution of the alcohol prepared in part B (1 mmol) in dichloromethane (2 mL) is added via canula. After an additional 15 min, diisopropylethylamine (4.5
30 mmol) is added and the reaction is gradually warmed to room temperature over 1 h and quenched with aqueous sodium bisulfate. The mixture is diluted with ether (50 mL) and is washed with water (2 x 30 mL), saturated aqueous brine (2 x 30 mL), is dried over magnesium sulfate and concentrated in vacuo.
35 The residue is purified by flash chromatography to afford 85.

II. General procedure for the conversion of (85) to tetraene (86).

D. Phosphonium salt 75 (0.2 mmol) is dissolved in anhydrous tetrahydrofuran (2 mL) and chilled to 0 °C. A solution of potassium bis(trimethylsilyl)amide (0.2 mmol, 0.5 M in tetrahydrofuran) is added and the reaction mixture is stirred 30 min at 0 °C. After cooling to -78 °C, a solution of aldehyde 85 (0.1 mmol) in tetrahydrofuran (2 mL) is added and the mixture is stirred 10 min at -78 °C and 2 h at room temperature. Saturated aqueous ammonium chloride (2 mL) is added and the resultant mixture is extracted with ether (3 x 20 mL). The ethereal layer is washed with water (2 x 25 mL) and saturated aqueous brine (25 mL), dried over magnesium sulfate and concentrated in vacuo. The residue is purified by flash chromatography to afford a tetraene.

E. To a solution of the tetraene prepared in part D (0.050 mmol) in dichloromethane (3 mL) at 0 °C is added water (0.050 mL) and 2,3-dichloro-5,6-dicyano-1,4-benzoquinone (0.018 mmol). After 1 h, the reaction mixture is diluted with ethyl acetate (50 mL), washed with saturated aqueous brine (3 x 25 mL), dried over magnesium sulfate and concentrated in vacuo. The residue is purified by flash chromatography to afford an alcohol.

F. To a solution of the alcohol prepared in part E (0.010 mmol) in dichloromethane (2 mL) is added trichloroacetyl isocyanate (1.00 mmol). After 30 min, the reaction mixture is diluted with dichloromethane (4 mL) and neutral alumina (1 g) is added. The resultant suspension is stirred an additional 4 h. The reaction mixture is filtered and the concentrated filtrate is chromatographed on silica gel to afford a carbamate.

G. Analog 86.

A solution of the carbamate prepared in part F (0.010 mmol) in 48% hydrofluoric acid-acetonitrile (1:9, 2 mL) is stirred at ambient temperature. After 12 h, saturated aqueous sodium bicarbonate (25 mL) is added and the mixture is

extracted with ethyl acetate (3 x 20 mL). The combined organics are dried over magnesium sulfate and concentrated in vacuo. The residue is purified by flash chromatography to afford **86**.

- 5 **Aldol (-)-5:** *PMB protection:* *p*-Methoxybenzyl alcohol (200 g, 1.45 mol) was added to a suspension of NaH (60% in mineral oil; 5.82 g, 0.146 mol) in anhydrous ether (450 mL) over 1 h at room temperature. The mixture was stirred 1 h further and cooled to 0 °C.
- 10 Trichloroacetonitrile (158 mL, 1.58 mol) was then introduced over 80 min. After 1.5 h the solution was concentrated with the water bath temperature maintained below 40 °C. The residue was treated with a mixture of pentane (1.5 L) and MeOH (5.6 mL), stirred at room temperature for 30 min, and
- 15 filtered through a short Celite column. Concentration gave the trichloroimide (370.9 g) as a yellow oil which was used without further purification.

- A solution of Roush's ester (+)-6 (129.0 g, 1.09 mol) in CH₂Cl₂/cyclohexane (1:2, 1.5 L) was cooled to 0 °C
- 20 and treated with crude trichloroimide (370.9 g) and PPTS (13.69 g, 55.0 mmol) over 0.5 h. After 3 h, the mixture was warmed to room temperature, stirred for 40 h, and concentrated. Suction filtration through a short silica plug (5 X 6 '' sintered glass funnel; 20% ethyl
- 25 acetate/hexanes) afforded the corresponding PMB ether (234.2 g) as a pale yellow oil which was divided into two portions for the next reaction.

- Reduction:* A solution of the above PMB ether (116.1 g) in anhydrous THF (800 mL) was cooled to 0 °C and added via
- 30 cannula to a solution of LiAlH₄ (0.67 M in THF, 800 mL, 0.536 mol) over 1 h (150 mL THF rinse), warmed gradually to room temperature, and stirred for 1 h. The reaction mixture was cooled to 0 °C and quenched via dropwise addition of H₂O (20 mL), 15% NaOH (20 mL), then H₂O (60 mL). The resultant mixture
- 35 was then treated with MgSO₄ (10 g), filtered (100 mL Et₂O rinse), and concentrated, furnishing a red oil (91.0 g). The

remaining 118.1 g was processed using the same protocol to yield an additional 94 g, yielding a total of 185 g of the corresponding alcohol(+)-8, which was divided into three portions for the next two reactions.

5 Swern: A solution of DMSO (72.1 mL, 1.02 mol) in CH_2Cl_2 (1.5 L) was cooled to -78°C and oxalyl chloride (44.3 mL, 0.51 mmol) was added over 30 min (internal temp $< -65^\circ\text{C}$). After an additional 30 min, a solution of the above alcohol (71.2 g, 0.338 mol) in CH_2Cl_2 (100 mL) was added
10 dropwise via cannula down the side of the flask over 30 min (20-mL rinse). The resultant mixture was stirred 45 min further at -78°C , then $i\text{-Pr}_2\text{NEt}$ (345 mL, 2.03 mol) was added over 45 min. The mixture was stirred 30 min further at -78°C then slowly warmed to 0°C (internal temp) via removal of
15 the external cooling bath. The reaction was quenched via addition to a vigorously stirred aqueous NaHSO_4 solution (1.0 M, 2.0 L). The layers were separated, the aqueous phase extracted (3 X Et_2O). The combined organic layers were concentrated (30°C water bath), diluted with ether
20 (1000 mL), washed with aqueous NaHSO_4 (3 X), water (1 X), saturated aqueous NaHCO_3 (1 X), and brine (1 X). The combined organic layers were dried over MgSO_4 , filtered and concentrated to give the corresponding aldehyde (70.5 g, ca. 100%) as a colorless oil.

25 *Evans Aldol Reaction:* A solution of oxazolidinone
61 (90.7 g, 389 mmol) in degassed CH_2Cl_2 (972 mL, 4 Å MS dried, argon sparged) was cooled to -55°C (internal temp) and $n\text{-Bu}_4\text{BOTf}$ (1.0 M in CH_2Cl_2 , 403 mL) was introduced over 0.5 h, followed by addition of NEt_3 (61.3 mL, 440 mmol) over 20
30 min. The mixture was warmed to 0°C (internal temp), stirred for 10 min, and cooled to -70°C . A degassed solution of above aldehyde (70.5 g, 0.338 mmol) in CH_2Cl_2 (200 mL) was then added via a cannula down the side of the flask over 1 h (20 mL rinse). After an additional 1.0 h at -78°C ,
35 the reaction was warmed to -8°C , stirred for 1 h, then

quenched with pH 7 potassium phosphate monobasic-sodium hydroxide buffer (0.05 M, 220 mL). A solution of 30% H₂O₂ in MeOH (1:2, 700 mL) was added to the vigorously stirred reaction mixture at such a rate as to maintain an internal temp < 8 °C (60 min, -10 °C cooling bath). The reaction was stirred 10 h at room temperature, and concentrated to ca. 1000 mL. The residue was dissolved in 1500 mL of 10:1 Et₂O/CH₂Cl₂, and the resulting layers were separated. The aqueous layer was extracted (3 X 10:1 Et₂O/CH₂Cl₂), and the combined organic layers were washed with saturated aqueous NaHCO₃ (1000 mL), water (1000 mL) and saturated brine (2 x 500 mL). The organic layer was dried over MgSO₄, filtered and concentrated to ca. 400 mL (3 X using a 2000 mL rb). The resulting white solid was filtered and dried overnight to give analytically pure **62** (83.8g, 56%). The combined mother liquors were concentrated and recrystallized from Et₂O to give an additional 10.0 g (7.0%, total yield of 63%) of **62**. The remaining 120 g of precursor alcohol was processed through the above two steps to give an additional 155.4 of **62** for a total of 249.2 g (52% yield over 4 steps). X-ray quality crystals were grown by recrystallization from ether-hexanes: mp 111.5-113.0 °C; [α]_D²³, +34.3°; IR (CHCl₃) 3600-3400 (br), 1780, 1705 cm⁻¹; ¹H NMR (500 MHz, CDCl₃) δ 7.42-7.33 (m, 3 H), 7.28-7.21 (m, 4 H), 6.85 (m, 2 H), 5.59 (d, J = 6.9 Hz, 1 H), 4.72 (quintet, J = 6.6 Hz, 1 H), 4.43 (s, 2 H), 3.92 (qd, J = 6.8, 3.4 Hz, 1 H), 3.88 (dd, J = 8.2, 3.4 Hz, 1 H), 3.76 (s, 3 H), 3.69 (br s, OH), 3.55 (m, 2 H), 1.95 (m, 1 H), 1.20 (d, J = 6.9 Hz, 3 H), 0.95 (d, J = 7.0 Hz, 3 H), 0.88 (d, J = 6.6 Hz, 3 H); ¹³C NMR (125 MHz, CDCl₃) δ 175.9, 159.3, 152.8, 133.3, 129.8, 129.4, 128.77, 128.7, 125.6, 113.8, 78.9, 75.6, 74.7, 73.2, 55.2, 55.1, 40.9, 36.0, 14.3, 13.6, 9.6; high resolution mass spectrum (CI) m/z 441.2133, [(M)+, calcd for C₂₅H₃₁NO₆Na: 441,2151].

To a solution of above Iodide in benzene/toluene (7:3, 5.0 mL) was added diisopropylethylamine (0.2 mL, 1.14 mmol) and triphenylphosphine (2.5 g, 9.53 mmol). (1.20g, 1.10 mmol; 8:1 ratio of diene isomers), was azeotropically dried with benzene (3 X 1.5 mL) using a double manifold and further dried by heating to 50 °C under vacuum (0.2 torr) for 12 h. The salt was dissolved in 6 mL of freshly distilled THF, sparged with argon for 15 min, and cooled to -20 °C. The resultant solution was treated with sodium bis(trimethylsilyl)amide (1.0 M in THF, 1.04 mL), stirred 15 min, warmed to 0 °C, stirred 30 min, and re-chilled to -24 °C. To this orange/red solution was transferred via cannula a degassed solution of aldehyde (-)-67 (508 mg, 1.14 mmol) in THF (3 mL + 1 X 0.5 mL rinse) over 7 min. The orange solution was allowed to slowly warm to -8 °C over 3.25 h. The resulting light yellow solution was quenched with saturated NH_4Cl , diluted with Et_2O and H_2O . The layers were separated, and the aqueous layer was extracted (3 X Et_2O). The combined organic layers were dried (Na_2SO_4), concentrated, and chromatographed (gradient

(+)-Discodermolide [1]. Carbamate (+)-60 (202 mg, 0.191 mmol) was dissolved in MeOH (70 mL) and stirred for 15
30 min at room temperature. Aqueous hydrochloric acid (3N, 40 mL) was added in 2-4 mL portions over 4 hours at a rate which minimized precipitation (ca. 10 to 15 min intervals). An additional 20 mL of 3 N aq HCl was added over 1 h at 15

After 8 h, an additional 20 mL of 3 N aq HCl was added in one portion, and the resulting solution was stirred for 2 h at rt, diluted with 350 mL of water and poured into 400 mL of EtOAc. The resulting layers were separated, and the aqueous layer was saturated with NaCl and extracted (3 X EtOAc). The combined organic layers were washed with saturated aqueous NaHCO₃ (2 X 100 mL) and saturated brine, dried (Na₂SO₄), filtered, and concentrated.

X-ray quality crystals were obtained by dissolving the amorphous solid in acetonitrile (0.1 M) at rt and allowing the solution to stand for several hours at rt: mp 108-111 °; $[\alpha]^{23}_D +16^\circ$ (c 0.033, MeOH); IR (CHCl₃) 3690, 3620, 3540, 3430, 1740 cm⁻¹; ¹H NMR (500 MHz, CDCl₃) δ 6.60 (dddd, J = 16.8, 8.4, 8.4, 0.8 Hz, 1 H), 6.02 (apparent t, J = 11.1 Hz, 1 H), 5.51 (dd, J = 11.2, 7.9 Hz, 1 H), 5.42 (ddd, J = 10.6, 10.6, 0.6 Hz, 1 H), 5.34 (apparent t, J = 10.4 Hz, 1 H), 5.20 (dd, J = 16.9, 1.9 Hz, 1 H), 5.16 (d, J = 10.0 Hz, 1 H), 5.11 (d, J = 10.1 Hz, 1 H), 4.77-4.69 (m, 1 H), 4.70 (dd, J = 7.3, 4.2 Hz, 1 H), 4.60 (ddd, J = 10.0, 10.0, 2.4 Hz, 1 H), 4.56 (br s, 2 H), 3.73 (m, 1 H), 3.28 (m, 1 H), 3.18 (dd, J = 6.8, 4.8 Hz, 1 H), 2.98 (ddq, J = 10.1, 6.9, 6.9 Hz, 1 H), 2.78 (ddq, J = 9.8, 6.8, 6.8 Hz, 1 H), 2.66 (qd, J = 7.3, 4.6 Hz, 1 H), 2.60-2.55 (m, 1 H), 2.10-1.80 (m, 10 H), 1.69 (ddd, J = 14.4, 10.3, 3.1 Hz, 1 H), 1.64 (d, J = 1.3 Hz, 3 H), 1.30 (d, J = 7.4 Hz, 3 H), 1.06 (d, J = 6.9 Hz, 3 H), 1.00 (d, J = 6.8 Hz, 3 H), 0.99 (d, J = 6.7 Hz, 3 H), 0.97 (d, J = 6.8 Hz, 3 H), 0.94 (d, J = 6.8 Hz, 3 H), 0.82 (d, J = 6.3 Hz, 3 H); ¹³C NMR (125 MHz, CDCl₃) δ 173.6, 157.0, 134.4, 133.7, 133.4, 132.9, 132.2, 129.9, 129.8, 117.9, 79.1, 78.9, 77.2, 75.7, 73.2, 64.4, 43.1, 41.0, 37.4, 36.1, 36.0, 35.8, 35.3, 34.8, 33.1, 23.3,

Example 76: Mesylate 1201.

5 To a solution of alcohol 1200 (0.032 mmol) in CH_2Cl_2 (1mL) was added triethylamine (7 μ L) and methanesulfonylchloride (4 μ L). After stirring for 1 hour 1 mL of sodium bicarbonate solution was added and the mixture was extracted (3x, CH_2Cl_2), dried ($MgSO_4$), filtered, and
10 concentrated. Purification was performed by flash chromatography (25% EtOAc/Hexanes) to provide 29 mg of mesylate 1201 (91%) as a clear oil.

Example 77: Isopropyl adduct 1206.

To a 0° C ethereal solution of mesylate 1201 (0.0269
15 mmol in 3 mL) was added $LiAlH_4$. The mixture was stirred for 45 min. and quenched with Rochelle's solution (5mL). The mixture was stirred for 30 min and extracted with Et2O (2x) and CH_2Cl_2 (2x). The combined organic extracts were washed (Brine), dried ($MgSO_4$), filtered, and concentrated. Flash
20 chromatography (10% EtOAc/Hexanes) provided 19 mg (80%) of the isopropyl adduct 1206 as a yellow oil.

Example 78: Propyl adduct 1202.

To a solution of CuI in THF (0.1 M) was added propylmagnesium bromide. The solution was stirred for 1 h
25 and a solution of mesylate 1201 added via cannula (THF). The reaction was stirred for 3 hours and quenched with sodium bicarbonate solution. The mixture was extracted with Et2O (2x) and CH_2Cl_2 (2x). The combined organic extracts were washed (sodium bicarbonate, brine), dried ($MgSO_4$),
30 filtered, and concentrated. Flash chromatography was performed (10%EtOAc/Hexanes) to provide the propyl adduct 1202.
